[TP] The figure shows how the partial pressures of the N_2O_4 and NO_2 **change with time** due to the chemical reaction

$$\text{N}_2\text{O}_4 \rightarrow 2 \text{NO}_2$$

for **certain initial conditions** (far left). At these **initial conditions**, the following is known about the chemical reaction.

25% 1. It is **spontaneous**
 25% 2. It is **at equilibrium**
 25% 3. It is **non-spontaneous**
 25% 4. Its spontaneity is **not known** without further information

Reaction quotient Q measures progress

For $\text{A} \rightarrow \text{B} + \text{C}$, the **reaction quotient** is ...

$$Q = \frac{[\text{B}][\text{C}]}{[\text{A}]}$$

The numerical value of the reaction quotient when the concentrations have their **equilibrium values** ...

$$[\text{A}]_e, [\text{B}]_e \text{ and } [\text{C}]_e$$

and so no longer change with time, is called the **equilibrium constant** ...

$$K = \frac{[\text{B}]_e[\text{C}]_e}{[\text{A}]_e}$$

6

Q versus K is the key to assessing spontaneity

If $Q < K$, product must form to get to equilibrium,
 so **spontaneous**

If $Q > K$, reactants must form to get to equilibrium,
 so **nonspontaneous**

So, Q/K is the **key** quantity to monitor.

$\text{N}_2\text{O}_4 \rightarrow 2 \text{NO}_2$

The **reaction quotient** is

$$Q = [\text{NO}_2]^2 / [\text{N}_2\text{O}_4]$$

The numerical value of the reaction quotient when the concentrations have their **equilibrium values**

$$[\text{N}_2\text{O}_4]_e \text{ and } [\text{NO}_2]_e$$

and so no longer change with time, is called the **equilibrium constant**

$$K = [\text{NO}_2]_e^2 / [\text{N}_2\text{O}_4]_e$$
