Begin ch16: Electron transfer reactions and electrochemistry

- Electrochemistry in a nutshell
- Electrochemical cells harness spontaneity as electron flow
- Cell line notation
- Cell voltage,  $E_{cell}$ , and electrical energy
- What determines cell voltage,  $E_{cell}$ ?

Next lecture: Continue ch16: What determines cell voltage,  $E_{cell}$ ?  
Calculating standard cell voltage,  $E^\circ_{cell}$ . Cell voltage versus spontaneity.

For **oxidation numbers** and **balancing redox equations**, please work through <http://goo.gl/MMEUCs>.

### Electrochemistry in a nutshell

- Redox processes **transfer electrons**
- Redox processes **evolve spontaneously** to equilibrium
- Electron transfer can be **harnessed as an electric current**

### $\text{Cu}^{2+}(aq)$ oxidizes $\text{Zn}(s)$

Spontaneous flow of electrons from Zn to Cu

$$\text{Cu}^{2+}(aq) + 2 e^- \rightarrow \text{Cu}(s)$$

$$\text{Zn}(s) \rightarrow \text{Zn}^{2+}(aq) + 2 e^-$$

Harness in an electrochemical cell

$$\text{Zn}(s) | \text{Zn}^{2+}(aq) || \text{Cu}^{2+}(aq) | \text{Cu}(s)$$

BOSTON UNIVERSITY

### Galvanic (Voltaic) Cells

Zn is oxidized to  $\text{Zn}^{2+}$  at anode.

$$\text{Zn}(s) \rightarrow \text{Zn}^{2+}(aq) + 2e^-$$

$\text{Cu}^{2+}$  is reduced to Cu at cathode.

$$2e^- + \text{Cu}^{2+}(aq) \rightarrow \text{Cu}(s)$$

Net reaction

$$\text{Zn}(s) + \text{Cu}^{2+}(aq) \rightarrow \text{Zn}^{2+}(aq) + \text{Cu}(s)$$

### Cell line notation (Tro, 4e, p 897)

- Oxidation on left, “||” is salt bridge, reduction on right
- Phases separated by “|”, same phases separated by “,”
- If no solid, inert electrode (Pt or graphite)
- Left to right order matches flow of electrons

### Cell voltage, $E_{\text{cell}}$ , and electrical energy

Electron flow in a voltage  $E$  is able to provide electrical energy

$$w_e = \text{electrical charge} \times \text{voltage}$$

In terms of moles of electrons that flow,  $n_e$ , the amount of charge is

$$\text{electrical charge} = n_e \times F$$

where  $F$ , known as the Faraday constant, is 96485 C/mol.

### Cell voltage, $E_{\text{cell}}$ , and electrical energy

A typical physiological voltage is  $0.150 \text{ V} = 0.150 \text{ J/C}$ .

The corresponding energy due to the transfer of 1.00 mol of electron is ...

$$w_e = \text{electrical charge} \times \text{voltage} = n_e F E_{\text{cell}}$$

$$= 1.00 \text{ mol} \times 0.150 \text{ J/C} \times 96485 \text{ C/mol}$$

$$= 14.5 \text{ kJ}$$

This is **a lot of energy!**

While each electron contributes a small amount of energy, there are **a lot of electrons in a mole!**

### What determines cell voltage, $E_{\text{cell}}$ ?

The bigger,  $E_{\text{cell}}$ , the more energy than can be harnessed.

Two things determine  $E_{\text{cell}}$ : **enthalpy change** and **spontaneity**

We will see that these two things together determine what is called the **free energy change,  $\Delta G$** , of the redox process.

**BOSTON UNIVERSITY**

45

Lecture 25 CH102 A1 (MWF 9 am) Spring 2017 Copyright © 2016 Dan Dill dan@bu.edu

### What determines cell voltage, $E_{\text{cell}}$ ?

By our convention that work done **on** the system corresponds to **positive energy change**, free energy change is defined with a negative sign ...

$$\Delta G_{\text{cell}} = -n_e F E_{\text{cell}}$$

so that **negative values of free energy change** mean work is available to be **done on the surrounding**.

The term "**free**" energy change reflects the fact that  $\Delta G$  is the energy **available** ('free') to do work.

In general, if  $\Delta G_{\text{cell}} < 0$ , that is, if  $E_{\text{cell}} > 0$ , then the redox process is able to **provide energy to the surroundings**.

## What determines cell voltage, $E_{\text{cell}}$ ?

We know spontaneity is determined by  $Q$  relative to  $K$ .

For now we can simplify things by arranging for  $Q = 1$ , typically by making reactants and products be in their **standard state**.

This arrangement defines what we call the **standard** free energy change,

$$\Delta G_{\text{cell}}^{\circ} = -n_e F E_{\text{cell}}^{\circ}$$
