Experiment 6 · Calorimetry

Pre-lab questions
*Answer these questions and hand them to the TF before beginning work.*

(1) What is the purpose of this experiment?
_________________________________________________________________________________________________________
_________________________________________________________________________________________________________

(2) How is heat $q$ related to enthalpy change $\Delta H$ at constant pressure?
_________________________________________________________________________________________________________
_________________________________________________________________________________________________________

(3) You will determine the calorimeter constant $c_{cal}$ of your calorimeter. What property of a calorimeter does $c_{cal}$ measure?
_________________________________________________________________________________________________________
_________________________________________________________________________________________________________

(4) You will measure the enthalpy change $\Delta H$ at constant pressure of several processes. Will these $\Delta H$ values be positive or negative? Will heat be absorbed or released?
_________________________________________________________________________________________________________
_________________________________________________________________________________________________________

(5) You will calculate several temperature changes $\Delta T$ using the formula $\Delta T = T_{mix} - T_i$. How will you determine the value of $T_{mix}$?
_________________________________________________________________________________________________________
_________________________________________________________________________________________________________
Calorimetry

Mathematical development

The calorimeter constant $C_{cal}$

Calorimetry is the science of measuring the quantities of heat released or absorbed during a chemical reaction. The amount of heat that flows in or out of a system depends on (1) the quantity of matter that constitutes the system, (2) the identity of that matter, and (3) temperature change experienced by the system as it absorbs or releases heat. In equation form

$$q = mC\Delta T$$

where $q$ represents heat, $m$ is the mass of the system, $C$ is the heat capacity of the system, and $\Delta T$ is the temperature change. The heat capacity $C$ is a measure of how a substance responds to the absorption or release of heat; substances that have a low value of $C$ such as iron ($C = 0.45 \text{ J/(g·°C)}$) tend to be good conductors of heat whereas substances that have a high value of $C$ such as water ($C = 4.18 \text{ J/(g·°C)}$) tend to be good insulators.

A vessel called a calorimeter is needed to hold the substances under study. Ideally, the calorimeter is a perfect insulator, that is, it should prevent the loss of heat from the system to the surroundings and it should not allow heat from the surroundings to enter the system. In practice, this state of affairs is extremely difficult to achieve: heat is inevitably exchanged between the system and the surroundings.
Consider what happens when a quantity of hot water is poured into a quantity of cold water inside a calorimeter. The following relationship accounts for the heat exchanged:

\[
\text{heat lost by the hot water} = \text{heat gained by the cold water} + \text{heat gained by the calorimeter}
\]

This relationship is expressed symbolically as

\[
-q_{hw} = q_{cw} + q_{cal} \\
-m_{hw}C_{hw}\Delta T_{hw} = m_{cw}C_{cw}\Delta T_{cw} + c_{cal}\Delta T_{cw} \quad \text{(Eqn. 6-1)}
\]

where \( m_{hw} \) is the mass of the hot water, \( m_{cw} \) is the mass of the cold water, \( C_{hw} \) is the heat capacity of the hot water, \( C_{cw} \) is the heat capacity of the cold water, \( \Delta T_{hw} \) is the temperature change experienced by the hot water as a result of mixing with the cold water, \( \Delta T_{cw} \) is the temperature change experienced by the cold water as a result of mixing with the hot water, and \( c_{cal} \) denotes the calorimeter constant, which is a measure of the calorimeter’s ability to act as an insulator.

We now employ the substitutions

\[
m_{hw} = \rho_{hw}V_{hw} \quad \text{and} \quad m_{cw} = \rho_{cw}V_{cw}
\]

where \( \rho \) represents density and \( V \) represents volume. For the sake of simplicity we ignore the fact that the density and the heat capacity of water vary with temperature; thus,

\[
\rho_{cw} = \rho_{hw} = \rho_w \quad \text{and} \quad C_{cw} = C_{hw} = C_w
\]

Plugging these substitutions into Eqn. 6-1 and solving for \( c_{cal} \) gives

\[
c_{cal} = -\rho_wC_w\left[V_{hw}\left(\frac{\Delta T_{hw}}{\Delta T_{cw}}\right)+V_{cw}\right]
\]

Inserting the numerical values \( \rho_w = 1.00 \text{ g/mL} \) and \( C_w = 4.18 \text{ J/(g\text{·°C})} \) gives
You use a slightly modified version of Eqn. 6-2a to compute $\mathcal{C}_{cal}$ of your calorimeter.

**The molar enthalpy change of reaction $\Delta H$**

At constant pressure, the heat in or out of a system is equal to the enthalpy change $\Delta H$. No special arrangement is needed to guarantee that the experiment takes place at constant pressure: the atmosphere automatically provides a constant pressure of 1 atm.

Suppose that the system consists of a salt MB(s) that absorbs heat when it dissolves in water in a calorimeter:

$$\text{MB(s) + heat } \rightarrow \text{MB(aq)}$$

The following relationship accounts for the heat exchanged:

heat gained by the system = heat lost by the solution + heat lost by the calorimeter (i.e., by the salt)

At constant pressure, this heat equation can be expressed as

$$q_{sys} = -q_{soln} - q_{cal}$$

$$\Delta H_{sys} = -m_{soln}C_{soln}\Delta T - \mathcal{C}_{cal}\Delta T$$  \hspace{1cm} (Eqn. 6-3a)

where $\Delta H_{sys}$ is the enthalpy change of the system (i.e., the salt), $m_{soln}$ is the mass of the solution, $C_{soln}$ is the heat capacity of the solution, $\Delta T$ is the temperature change experienced by the solution as a result of the dissolution of the salt, and $\mathcal{C}_{cal}$ is the calorimeter constant.

To make the measurement of $\Delta H_{sys}$ more meaningful, it is customary to report its value on a per-mole basis. Thus, we are really interested in $\Delta H_{sys}/n_{sys}$, where $n_{sys}$ is the number of moles of salt that dissolve. We will give the quantity $\Delta H_{sys}/n_{sys}$ the symbol $\Delta \tilde{H}$. Because the number of moles $n$ of a substance is related to the mass $m$ of that substance and to its molar mass $\mathcal{M}$ by
\[ n = \frac{m}{M} \]

dividing both sides of Eqn. 6-3a by \( n_{sys} \) and making the substitutions \( \Delta H_{sys}/n_{sys} = \Delta \mathcal{H} \) and \( n_{sys} = m_{sys}/M_{sys} \) gives

\[
\Delta \mathcal{H} = - \frac{m_{soln}C_{soln}\Delta T + \epsilon_{cal}\Delta T}{m_{sys}/M_{sys}} \quad (Eqn. \ 6-4)
\]

As before, the mass \( m_{soln} \) of the salt solution can be related to its density and its volume:

\[
m_{soln} = \rho_{soln}V_{soln}
\]

For simplicity, we assume that the aqueous salt solution is so dilute that its density \( \rho_{soln} \) and heat capacity \( C_{soln} \) are the same as those of pure water, that is, \( \rho_{soln} = \rho_w = 1.00 \text{ g/mL} \) and \( C_{soln} = C_w = 4.18 \text{ J/(g\degreeC)} \). Substituting these values into Eqn. 6-4 gives

\[
\Delta \mathcal{H} = - \left( \frac{M_{sys}\Delta T}{m_{sys}} \right) \left[ \frac{4.18 \text{ J}}{\text{mL\degreeC}} \right] V_{soln} + \epsilon_{cal} \quad (Eqn. \ 6-5)
\]

You use Eq. 6-5 to compute the value of the molar enthalpy change \( \Delta \mathcal{H} \) of a variety of reactions.

**Procedure**

**Determination of \( \mathcal{C}_{cal} \)**

The first part of the lab session is devoted to evaluating \( \mathcal{C}_{cal} \) of your calorimeter. You use an aluminum vessel as a calorimeter. The solutions that you are studying should be placed in the insulated inner cup of the calorimeter. The lid of the calorimeter is equipped with a cap (which should remain in place at all times), a thermometer, and a stirring ring (see Figure 6-1). It is essential that you use the same calorimeter for all your work.

Measure out about 50 mL of deionized water using a graduated cylinder. This volume corresponds to \( V_{cw} \) in Eqn. 6-
Do not boil the water too far ahead of the time that you will be ready to mix it with the cold water in the calorimeter.

If you add significantly less than 100 mL of boiling water, you will arrive at a value of \( C_{\text{cal}} \) that is negative, which is impossible.

Careful! The calorimeter may be quite hot. Put on heavy-duty gloves before attempting to remove the inner cup of the calorimeter.

2a; record the volume in your notebook. Pour the water into the inner cup of the calorimeter. Replace the lid and record the temperature of the water at 30-sec intervals until it stabilizes. Be sure that the thermometer is suspended near, but not touching, the bottom or sides of the inner cup. Call the temperature at which the water stabilizes the initial temperature of the cold water \( T_{cw,i} \); be sure to record it.

Using a Bunsen burner, bring about 100 mL of deionized water to a full boil in a beaker. Assume that the temperature of the boiling water is 100 °C; call this the initial temperature of the hot water \( T_{hw,i} \). Do not attempt to measure the temperature of the boiling water because you may destroy the temperature sensor in the thermometer in the process. Put on heavy-duty gloves, extinguish the burner, pour the boiling water into the calorimeter, replace the lid, and vigorously agitate the contents of the calorimeter by moving the stirring ring up and down. Record the temperature 30 sec after the hot water is added to the calorimeter and at 30-sec intervals thereafter for at least 5 min; agitate the contents of the calorimeter throughout the data acquisition period. You want to observe a temperature decrease: if you don’t, continue taking data past the recommended 5 min time period.

At the end of the data acquisition period, measure the total volume of water \( V_{\text{tot}} \) in the calorimeter using a graduated cylinder. The volume of hot water \( V_{hw} \) in Eqn. 6-2a equals the total volume of water in the calorimeter minus \( V_{cw} \) that is, \( V_{hw} = V_{\text{tot}} - V_{cw} \).

**Working up the \( C_{\text{cal}} \) data**

In your notebook prepare a plot of your \( C_{\text{cal}} \) data, plotting time along the x axis and temperature along the y axis. Call the time when you added the hot water to the cold water \( t = 0 \). The plot should look like Figure 6-2. For maximum accuracy the plot should take up a full page in your notebook. **Do not wait to prepare this plot and to calculate \( C_{\text{cal}} \) at home after lab!** If your \( C_{\text{cal}} \) data is no good, you must know so immediately so that you can take remedial action.

The value of \( C_{\text{cal}} \) is computed from Eq. 6-2a:
\[ \mathcal{Q}_{cal} = -\left(\frac{4.18 \text{ J}}{\text{mL} \cdot ^\circ \text{C}}\right) \left[ V_{hw} \left( \frac{\Delta T_{hw}}{\Delta T_{cw}} \right) + V_{cw} \right] \]  

(Eqn. 6-2a)

You already measured \( V_{cw} \) and \( V_{hw} \). We now explain how the quantities \( \Delta T_{cw} \) and \( \Delta T_{hw} \) are determined. Let’s define

\[ \Delta T_{cw} = T_{cw,f} - T_{cw,i} \quad \text{and} \quad \Delta T_{hw} = T_{hw,f} - T_{hw,i} \]

\( T_{cw,i} \) and \( T_{hw,i} \) are the initial temperatures of the cold water and of the hot water, respectively; you already measured \( T_{cw,i} \) and you are assuming that \( T_{hw,i} = 100 \, ^\circ \text{C} \). \( T_{cw,f} \) and \( T_{hw,f} \) are the final temperatures reached by the cold water and the hot water, respectively. It’s clear that \( T_{cw,f} = T_{hw,f} \) because the two bodies of water will have been mixed. Let’s call this common final temperature of the mixture \( T_{mix} \). Thus, the quantities we are looking for are

\[ \Delta T_{cw} = T_{mix} - T_{cw,i} \quad \text{and} \quad \Delta T_{hw} = T_{mix} - T_{hw,i} \]

Use a ruler to draw a straight line through the data points lying on the downward sloping portion of the plot. Make sure that the line intercepts the vertical temperature axis erected at \( t = 0 \) (see Figure 6-2). The temperature \( T_{mix} \) corresponds to the \( y \)-intercept of the line and represents the temperature that the

**Figure 6-2** Hypothetical data collected during the measurement of \( \mathcal{Q}_{cal} \). The hot water is added to the cold water in the calorimeter at \( t = 0 \). The line drawn through the data points intercepts the vertical temperature axis at \( T_{mix} \).
mixture would have exhibited if mixing and heat exchange were instantaneous.

We are at last ready to calculate \( \epsilon_{cal} \) using Eqn. 6-2b, which is a more detailed version of Eqn. 6-2a:

\[
\epsilon_{cal} = -\left( \frac{4.18 \text{ J}}{\text{mL} \cdot \degree \text{C}} \right) \left[ V_{hw} \left( \frac{T_{mix} - 100\degree \text{C}}{T_{mix} - T_{cw,i}} \right) + V_{cw} \right] \tag{Eqn. 6-2b}
\]

\( \epsilon_{cal} \) must be a positive number. If you arrive at a negative number, you did something wrong. A common mistake is boiling the water too far ahead of the time, leading to the addition of significantly less than 100 mL of boiling water. Check your calculations or repeat the experiment. If on the second try you once again arrive at a \( \epsilon_{cal} \) that is negative and you’re sure that no errors have been committed, set \( \epsilon_{cal} \) equal to zero joules per degree Celsius and continue with the experiment.

**Experiment # 1**

**Determination of \( \Delta \mathcal{H} \) of \( \text{NH}_4\text{Cl}(s) \rightarrow \text{NH}_4^+(aq) + Cl^-(aq) \)**

Weigh out 3–4 g of ammonium chloride (\( \text{NH}_4\text{Cl}(s) \)). In your notebook record the exact mass taken. Measure out with a graduated cylinder about 100 mL of deionized water and place it in the calorimeter; record the exact volume in your notebook. Cover the calorimeter with the lid and record the temperature of the water in the calorimeter at 30-sec intervals until it stabilizes. We will call the temperature at which the water stabilizes the initial temperature \( T_{\text{soln},i} \); be sure to record it.

Once the temperature of the water in the calorimeter has stabilized, add the \( \text{NH}_4\text{Cl}(s) \) to the calorimeter, replace the lid, and agitate the contents of the calorimeter by moving the stirring ring up and down. Record the temperature 30 sec after the \( \text{NH}_4\text{Cl}(s) \) is added to the calorimeter and at 30-sec intervals thereafter for at least 5 min; agitate the contents of the calorimeter throughout the data acquisition period.

When you add the \( \text{NH}_4\text{Cl}(s) \), the temperature of the water in the calorimeter will go down. You must take data until you observe a temperature increase of at least a few tenths of a degree; you may have to collect data past the recommended 5 min time period.
At the end of the data acquisition period, dispose of the solution in a hazardous waste receptacle. Rinse out the calorimeter and dispose of the rinses in a hazardous waste receptacle.

Repeat the procedure in this section, but this time weigh out 4–5 g of NH₄Cl(s): you want data from two runs.

Experiment #2
Determination of ΔH of KCl(s) → K⁺(aq) + Cl⁻(aq)
Weigh out 3–4 g of potassium chloride (KCl(s)). Record the exact mass taken. Measure out with a graduated cylinder about 100 mL of deionized water and place it in the calorimeter; record the exact volume in your notebook. Cover the calorimeter with the lid and record the temperature of the water in the calorimeter at 30-sec intervals until it stabilizes. Call the temperature at which the water stabilizes the initial temperature $T_{soln,i}$; be sure to record it.

Once the temperature of the water in the calorimeter has stabilized, add the KCl(s) to the calorimeter, replace the lid, and agitate the contents of the calorimeter by moving the stirring ring up and down. Record the temperature 30 sec after the KCl(s) is added and at 30-sec intervals thereafter for at least 5 min; agitate the contents of the calorimeter throughout the data acquisition period.

When you add the KCl(s), the temperature of the water in the calorimeter will go down. You must take data until you observe a temperature increase of at least a few tenths of a degree; you may have to collect data past the recommended 5 min time period.

At the end of the data acquisition period, dispose of the solution in a hazardous waste receptacle. Rinse out the calorimeter and dispose of the rinses in a hazardous waste receptacle.

Repeat the procedure in this section, but this time weigh out 4–5 g of KCl(s): you want data from two runs.

Experiment #3
Determination of ΔH of
NH₄Cl(s) + KCl(s) → NH₄⁺(aq) + K⁺(aq) + 2 Cl⁻(aq)
Weigh out 3–4 g of NH₄Cl(s) and 3–4 g of KCl(s). In your notebook record the exact mass of each compound taken. Measure out with a graduated cylinder about 100 mL of deionized water
and place it in the calorimeter; record the exact volume in your notebook. Cover the calorimeter with the lid and record the temperature of the water in the calorimeter at 30-sec intervals until it stabilizes. We will call the temperature at which the water stabilizes the initial temperature $T_{\text{soln,}i}$ be sure to record it.

Once the temperature of the water in the calorimeter has stabilized, add the NH$_4$Cl(s) and the KCl(s) to the calorimeter, replace the lid, and agitate the contents of the calorimeter by moving the stirring ring up and down. Record the temperature 30 sec after the NH$_4$Cl(s) and the KCl(s) are added to the calorimeter and at 30-sec intervals thereafter for at least 5 min; agitate the contents of the calorimeter throughout the data acquisition period.

When you add the NH$_4$Cl(s) and the KCl(s), the temperature of the water in the calorimeter will go down. You must take data until you observe a temperature increase of at least a few tenths of a degree; you may have to collect data past the recommended 5 min time period.

At the end of the data acquisition period, dispose of the solution in a hazardous waste receptacle. Rinse out the calorimeter and dispose of the rinses in a hazardous waste receptacle.

Repeat the procedure in this section, but this time weigh out 4–5 g of NH$_4$Cl(s) and 4–5 g of KCl(s): you want data from two runs.

**Data analysis**

**Experiments # 1 and # 2**

You use Eq. 6-5 to compute the molar enthalpy change $\Delta \mathcal{H}$ of the reactions carried out in Experiment # 1 and # 2:

$$\Delta \mathcal{H} = - \left( \frac{M_{\text{sys}} \Delta T}{m_{\text{sys}}} \right) \left[ \left( \frac{4.18 \text{ J}}{\text{mL} \cdot ^\circ \text{C}} \right) V_{\text{soln}} + c_{\text{cal}} \right] \quad \text{(Eqn. 6-5)}$$

For Experiment # 1 the variable $M_{\text{sys}}$ refers to the molar mass of NH$_4$Cl ($M = 53.49$ g/mol) and the variable $m_{\text{sys}}$ refers to the mass of NH$_4$Cl used. For Experiment # 2 the variable $M_{\text{sys}}$ refers to the molar mass of KCl ($M = 74.55$ g/mol) and the vari-
able \( m_{sys} \) refers to the mass of KCl used. The variable \( V_{soln} \) refers to the volume of solution in the calorimeter.

The value of \( \Delta T \) is determined by the same technique employed in the measurement of \( \epsilon_{cal} \). Time is plotted along the \( x \) axis and temperature along the \( y \) axis. Call the time when you added the NH\(_4\)Cl(s) or the KCl(s) to the calorimeter \( t = 0 \). Draw a straight line through the data points lying on the upward sloping (i.e., increasing temperature) portion of the plot, making sure that the line intercepts the vertical temperature axis erected at \( t = 0 \). The temperature \( T_{mix} \) corresponds to the \( y \)-intercept of the line and represents the temperature that the mixture would have exhibited if mixing and heat exchange were instantaneous. In both experiments, \( \Delta T = T_{mix} - T_{soln,i} \). Note that \( \Delta T \) should be a negative number because \( T_{mix} < T_{soln,i} \).

**Experiment #3**

You use Eq. 6-3a to compute the enthalpy change \( \Delta H \) of the reaction carried out in Experiment #3:

\[
\Delta H = -m_{soln}C_{soln}\Delta T - \epsilon_{cal}\Delta T \quad \text{(Eqn. 6-3a)}
\]

Performing the substitution \( m_{soln} = \rho_{soln}V_{soln} \) and assuming that \( \rho_{soln} = 1.00 \) g/mL and \( C_{soln} = 4.18 \) J/(g·°C) gives Eqn. 6-3b, which is a more detailed version of Eqn. 6-3a:

\[
\Delta H = -\Delta T \left[ \left( \frac{4.18}{\text{mL} \cdot \text{°C}} \right) V_{soln} + \epsilon_{cal} \right] \quad \text{(Eqn. 6-3b)}
\]

The value of \( \Delta T \) is determined by the same technique employed in the measurement of \( \epsilon_{cal} \). Time is plotted along the \( x \) axis and temperature along the \( y \) axis. Call the time when you added the NH\(_4\)Cl(s) and the KCl(s) to the calorimeter \( t = 0 \). Draw a straight line through the data points lying on the upward sloping (i.e., increasing temperature) portion of the plot, making sure that the line intercepts the vertical temperature axis erected at \( t = 0 \). The temperature \( T_{mix} \) corresponds to the \( y \)-intercept of the line. Note that \( \Delta T = T_{mix} - T_{soln,i} \) should be a negative number because \( T_{mix} < T_{soln,i} \).
Experiment 6 · Calorimetry

Lab report form

Page 1

In (I.A), (II.A), (III.A), and (IV.A) you are asked to submit plots similar to Figure 6-2. Prepare a separate plot for each run. Give each plot a truly informative title (i.e., don’t just call it “Experiment 1, Run 1”), label the axes, and include appropriate units and divisions of those axes. Draw the straight line from which the value of $T_{\text{mix}}$ is determined and write the value of $T_{\text{mix}}$ on the plot. Do not submit small plots: use a whole sheet of paper. Scale the horizontal and vertical axes so that the data points occupy most of the area of the plot.

(I.A) Prepare a plot of the data collected in the measurement of $\varepsilon_{\text{cal}}$.

(I.B) Report the quantities needed for the calculation of $\varepsilon_{\text{cal}}$ according to Eqn. 6-2b:

$$
\varepsilon_{\text{cal}} = -\left(\frac{4.18}{\text{mL} \cdot ^\circ \text{C}}\right) \left[ V_{\text{hw}} \left( \frac{T_{\text{mix}} - 100 \, ^\circ \text{C}}{T_{\text{mix}} - T_{\text{cw},i}} \right) + V_{\text{cw}} \right] 
$$

(Eqn. 6-2b)

(IV.C) What are the units of $\Delta H$?
Post-lab questions

(1.a) Let $\Delta \mathcal{H}_{\text{NH}_4\text{Cl}}$ represent the mean value of $\Delta \mathcal{H}$ of $\text{NH}_4\text{Cl}(s) \rightarrow \text{NH}_4^+(aq) + \text{Cl}^-(aq)$ reported in (II.B), let $\Delta \mathcal{H}_{\text{KCl}}$ represent the mean value of $\Delta \mathcal{H}$ of $\text{KCl}(s) \rightarrow \text{K}^+(aq) + \text{Cl}^-(aq)$ reported in (III.B), and let $\Delta H$ represent the mean value of $\Delta H$ of $\text{NH}_4\text{Cl}(s) + \text{KCl}(s) \rightarrow \text{NH}_4^+(aq) + \text{K}^+(aq) + 2 \text{Cl}^-(aq)$ reported in (IV.B). Write a mathematical equation that shows how $\Delta \mathcal{H}_{\text{NH}_4\text{Cl}}$ and $\Delta \mathcal{H}_{\text{KCl}}$ are related to $\Delta H$.

(1.b) Confirm whether the data you collected in Experiment # 3 fits the equation you wrote in (1.a) by completing the following table. Show the calculation of $\Delta H$ according to the equation you wrote in (1.a) using data from your two runs in Experiment # 3 and calculate the percent error using

$$\text{percent error} = 100\% \times \frac{(\Delta H_{\text{calc}} - \Delta H_{\text{report}})}{\Delta H_{\text{report}}}$$

Calculation of $\Delta H$ according to the equation in (1.a) for Run # 1 in Experiment # 3:

Calculation of $\Delta H$ according to the equation in (1.a) for Run # 2 in Experiment # 3:
(1.c) Regardless of whether your data furnishes agreement or not, which experimental operations might contribute most to any observed discrepancy?

(2) In this experiment you measure enthalpy change $\Delta H$. You are not measuring standard enthalpy change $\Delta H^\circ$. Why are the enthalpy changes you measure not standard? (Consulting your lecture textbook may help in answering this question.)
